

# How to encode 20 amino acids from 4 nucleotides?

**2 nucleotide code yields  $4^2 = 16$  different combinations**

**3 nucleotide code yields  $4^3 = 64$  different combinations**

# The Genetic Code

(almost)

## •Universal

The same genetic code is used in bacterial, plants, fungal or animals genomes (exceptions)

## •Degenerate

Multiple sequences code for the same AA

## •Non-random

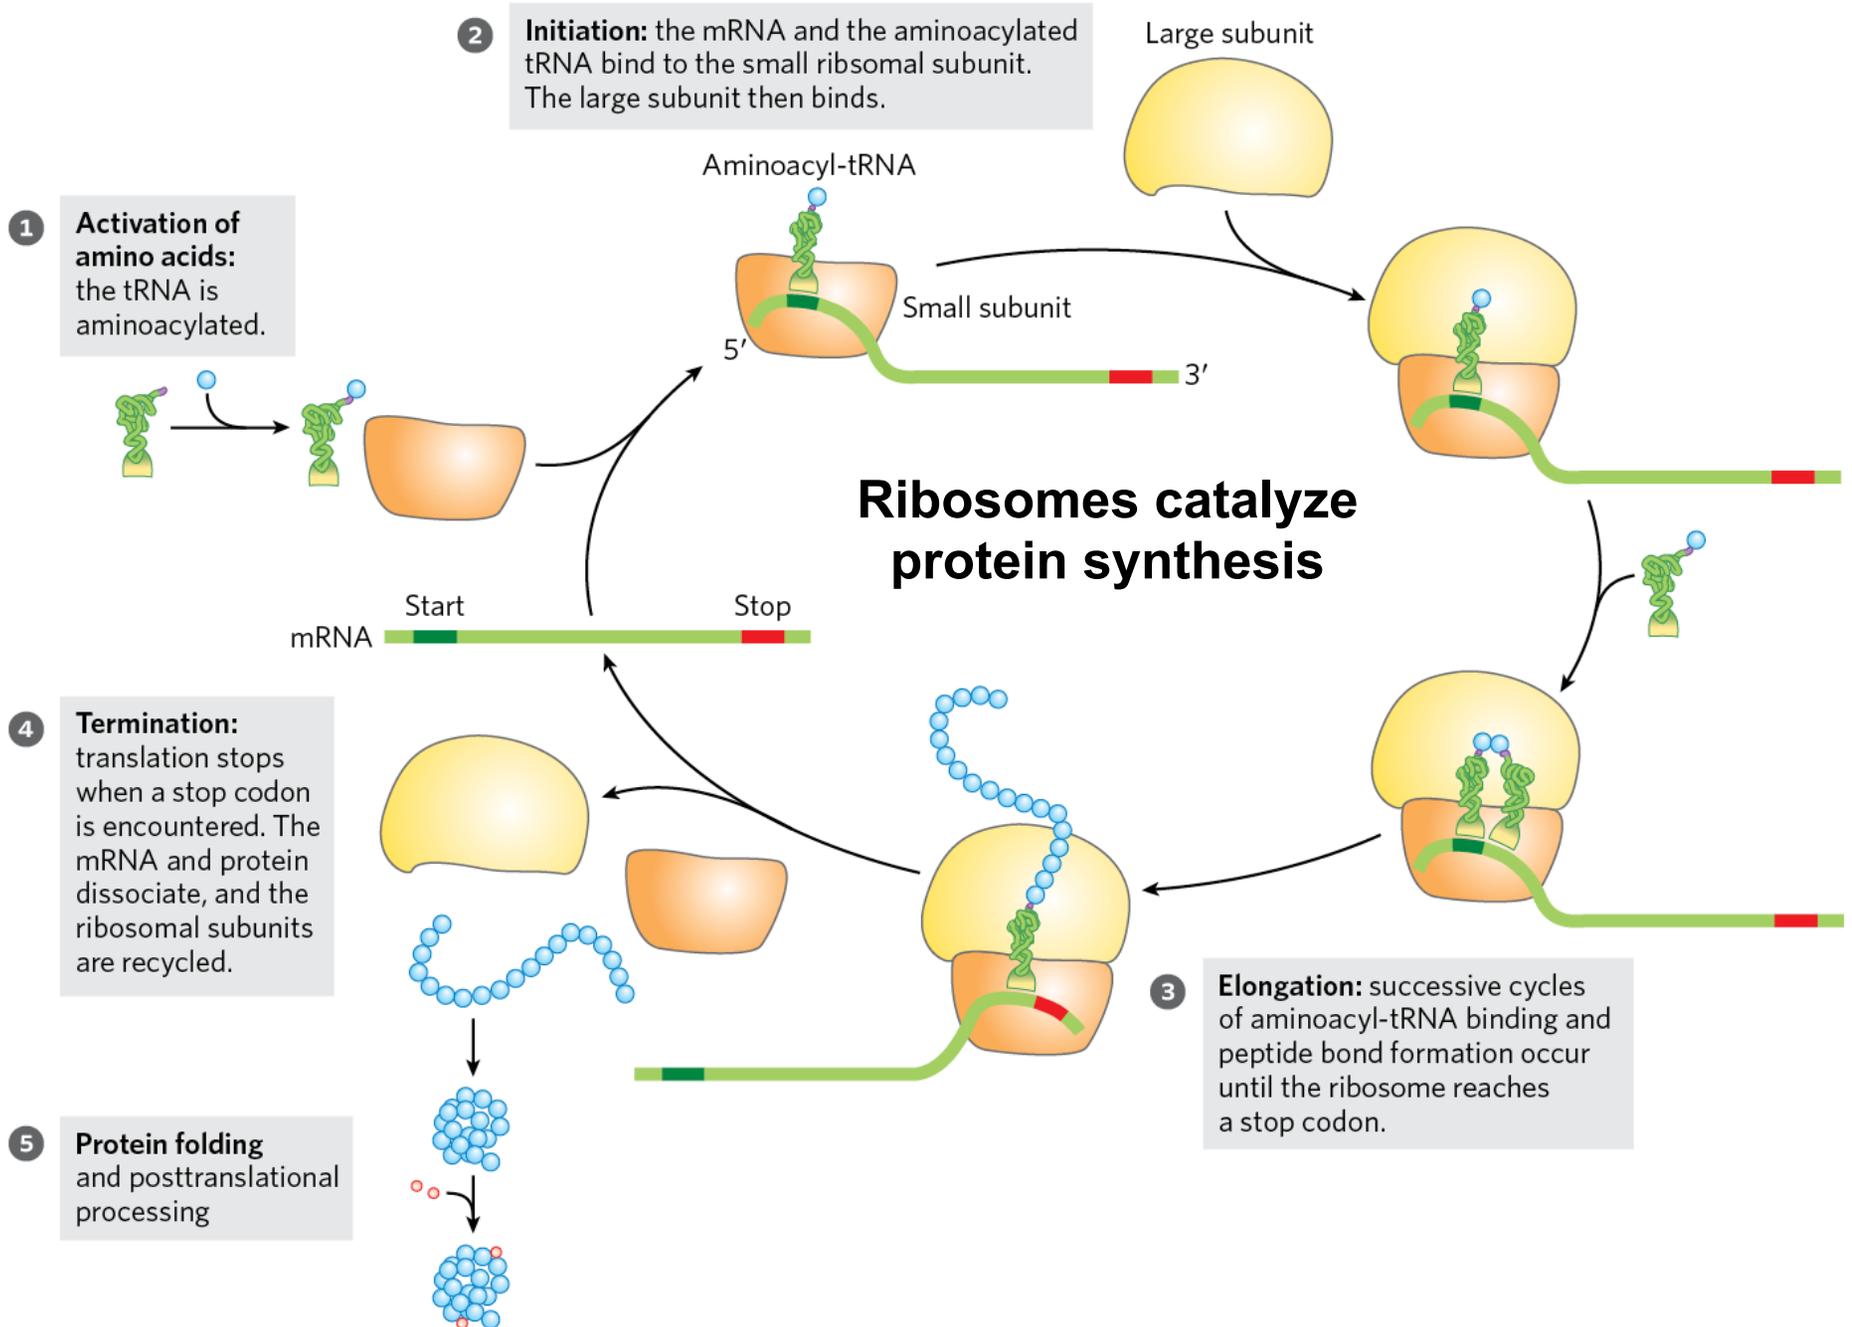

Single mutation of a codon is typically **neutral** (=> same AA) or **conservative** (results in a similar AA)

First position (5' end)	Second position				Third position (3' end)
	U	C	A	G	
<b>U</b>	UUU	UCU	UAU	UGU	<b>U</b> <b>C</b> <b>A</b> <b>G</b>
	UUC Phe	UCC Ser	UAC Tyr	UGC Cys	
	UUA Leu	UCA	UAA Stop	UGA Stop	
	UUG	UCG	UAG Stop	UGG Trp	
<b>C</b>	CUU	CCU	CAU	CGU	<b>U</b> <b>C</b> <b>A</b> <b>G</b>
	CUC Leu	CCC Pro	CAC His	CGC Arg	
	CUA	CCA	CAA Gln	CGA	
	CUG	CCG	CAG	CGG	
<b>A</b>	AUU	ACU	AAU	AGU	<b>U</b> <b>C</b> <b>A</b> <b>G</b>
	AUC Ile	ACC Thr	AAC Asn	AGC Ser	
	AUA	ACA	AAA Lys	AGA Arg	
	AUG Met <sup>b</sup>	ACG	AAG	AGG	
<b>G</b>	GUU	GCU	GAU	GGU	<b>U</b> <b>C</b> <b>A</b> <b>G</b>
	GUC Val	GCC Ala	GAC Asp	GGC Gly	
	GUA	GCA	GAA Glu	GGA	
	GUG	GCG	GAG	GGG	

<sup>a</sup>Nonpolar amino acid residues are tan, basic residues are blue, acidic residues are red, and polar uncharged residues are purple.

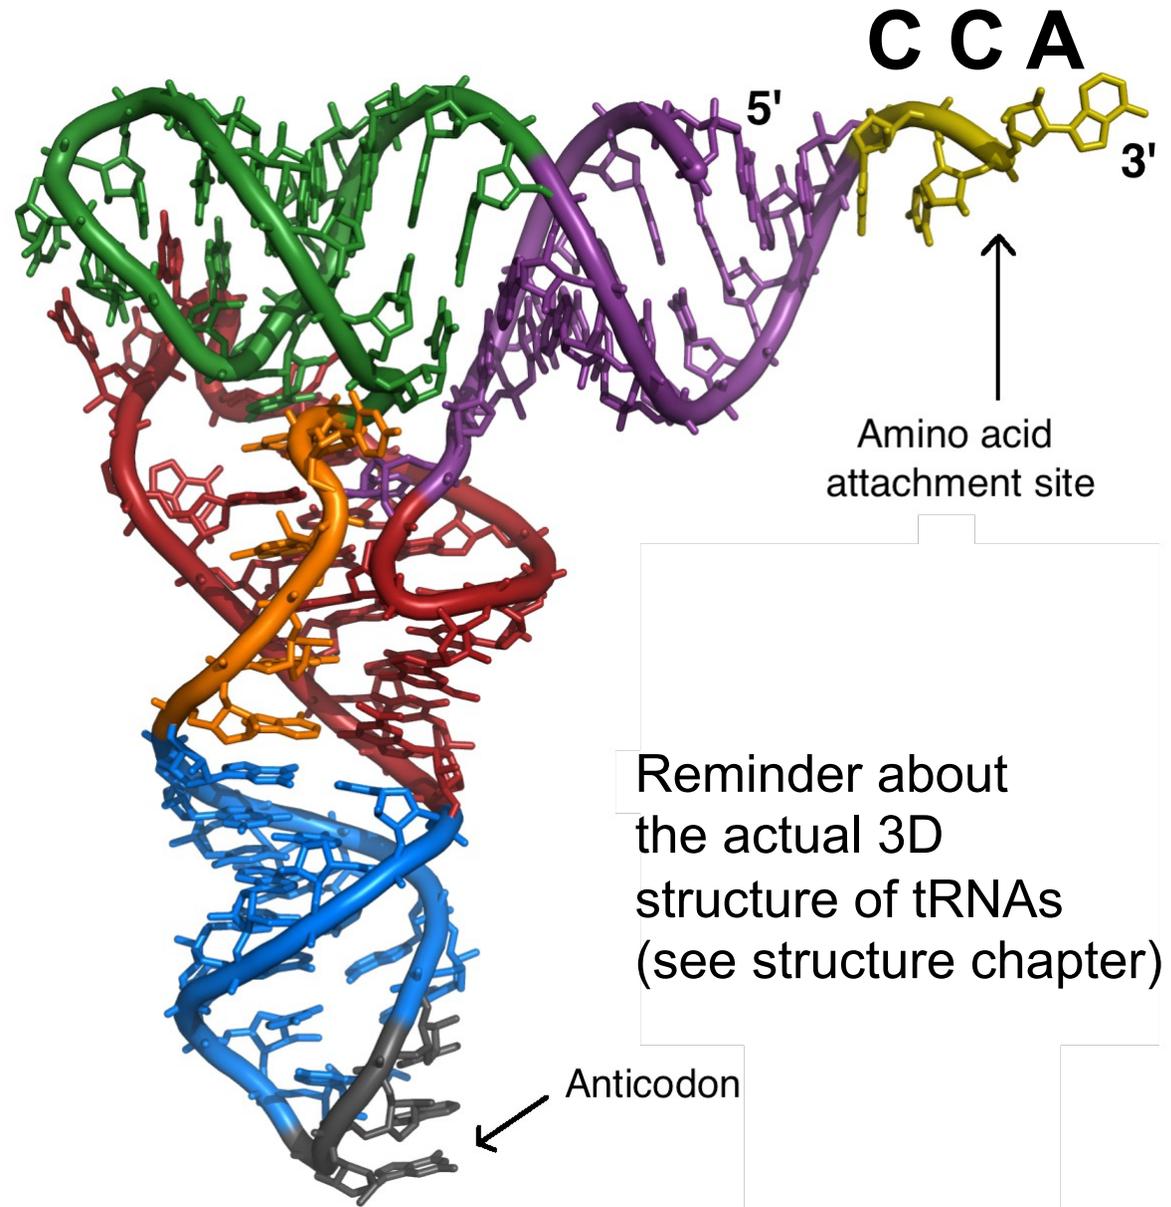

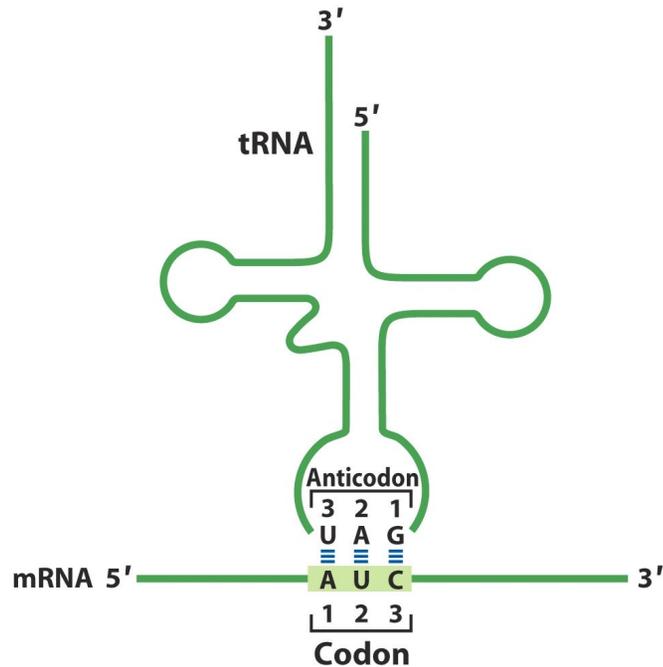

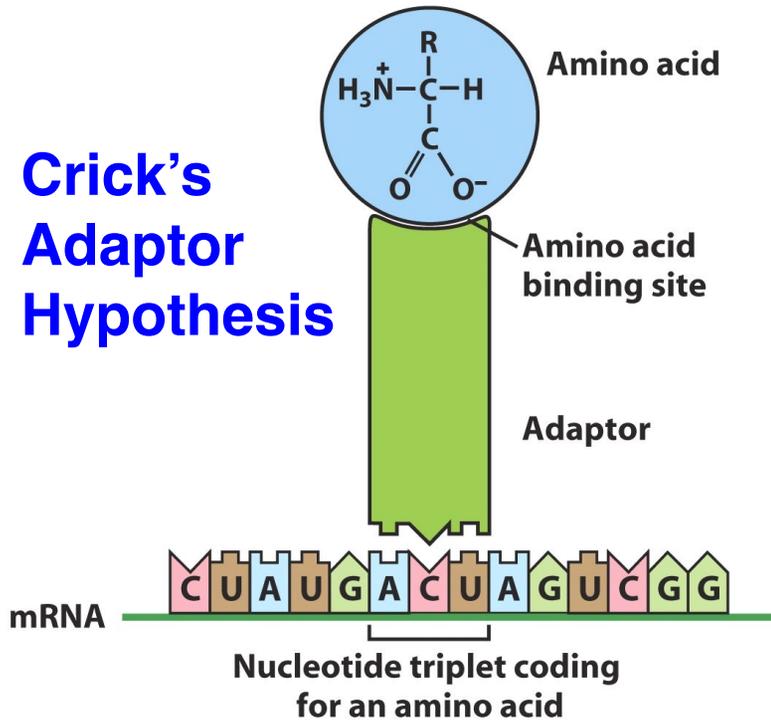

<sup>b</sup>AUG forms part of the initiation signal as well as coding for internal Met residues.

# An overview of protein synthesis

# tRNAs are adaptor molecules

## Crick's Adaptor Hypothesis

Reminder about the actual 3D structure of tRNAs (see structure chapter)

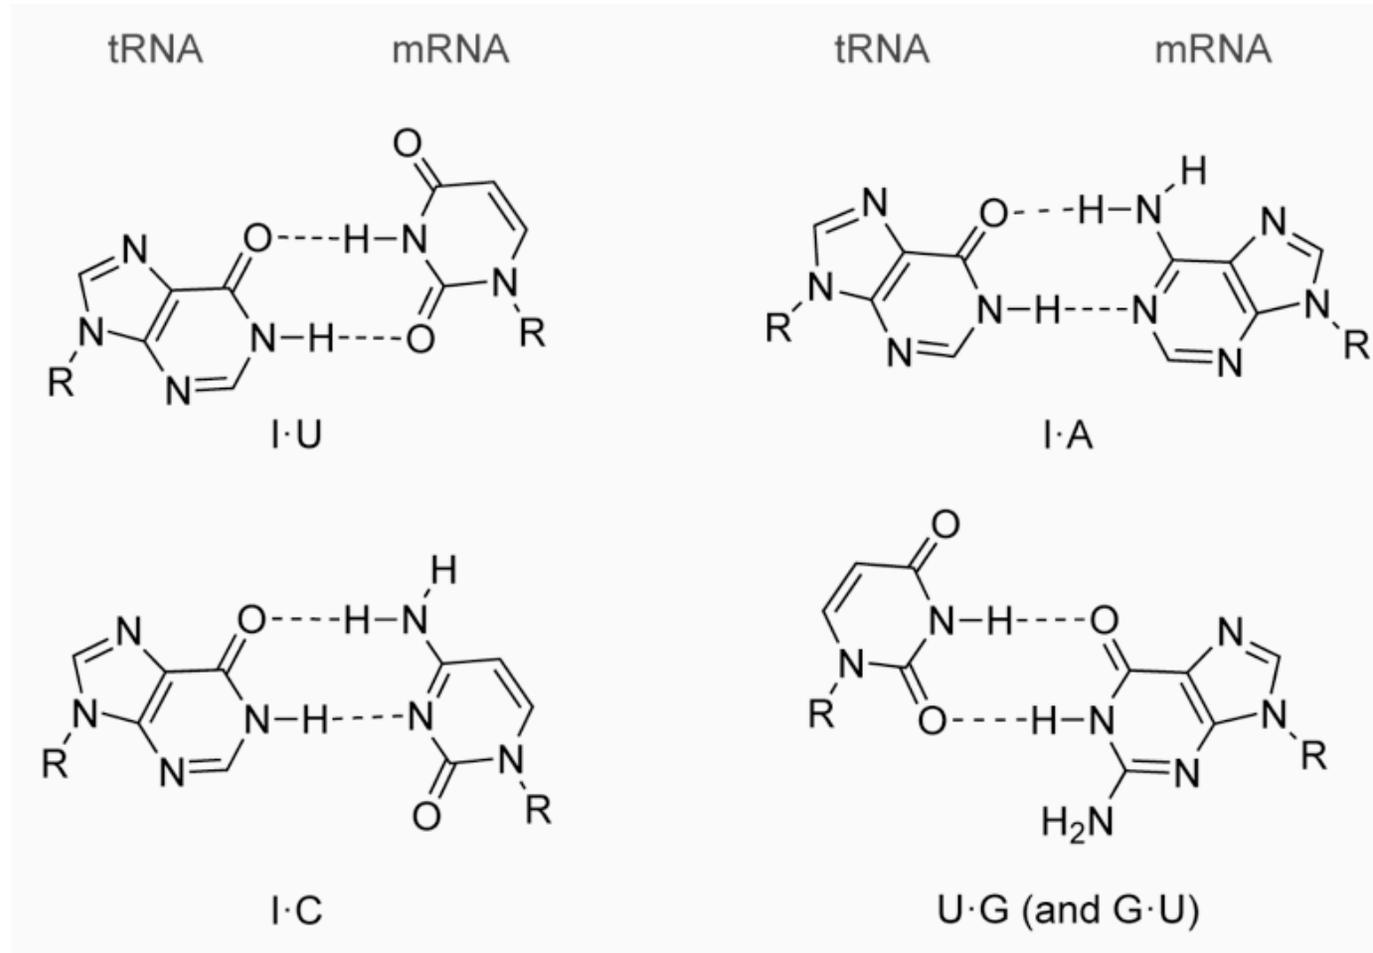

# One tRNA can recognize several codons by flexibility of base pairing (“wobble”) at position 3 of the mRNA codon

AntiCodon (1) (=tRNA)	Codon (3) (=mRNA)
C	can read G
A	can read U
U	can read A, G
G	can read C, U
I	can read C, U, A

tRNA Anticodon	3	2	1	tRNA Anticodon	3	2	1	tRNA Anticodon	3	2	1	
(3')	G	C	I	(3')	G	C	I	(5')	G	C	I	
	≡	≡	≡		≡	≡	≡		≡	≡	≡	
Codon mRNA	(5')	C	G	A	(5')	C	G	U	(5')	C	G	C
		1	2	3		1	2	3		1	2	3

CUU	CCU	CAU	His
CUC	CCC	CAC	
CUA	CCA	CAA	Gln
CUG	CCG	CAG	

Leu      Pro

**!** The wobble rule only applies to position 3 of the codon NOT to Positions 1 and 2

A tRNA has the anticodon 5'-GAA-3'. Which codons could it potentially recognize?

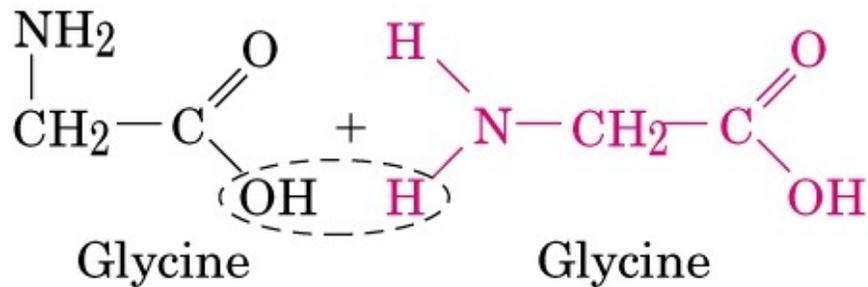

**A: UUC only**

**B: UUU and UUC**

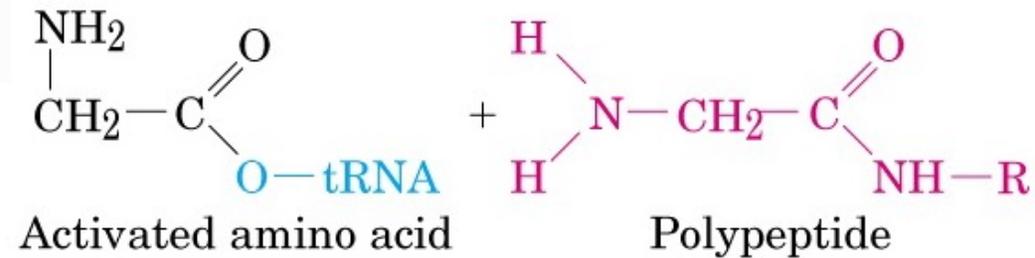

**C: UUU, UUC, and UUA**

**D: UUC and UUG**

# Biological Peptide Formation is NOT a condensation reaction

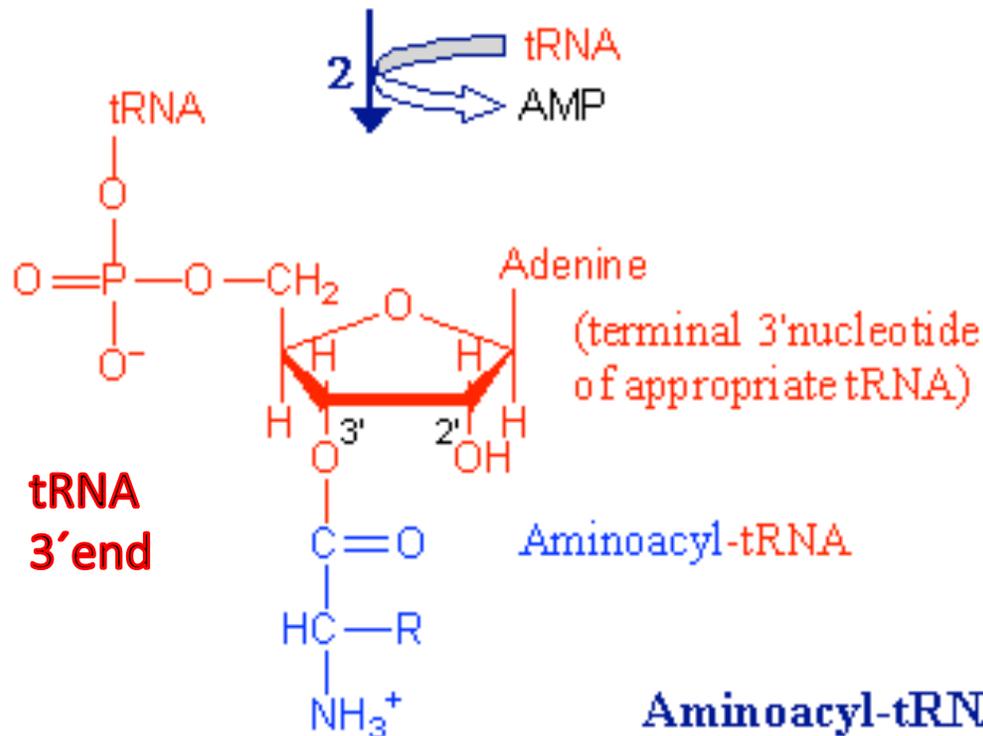

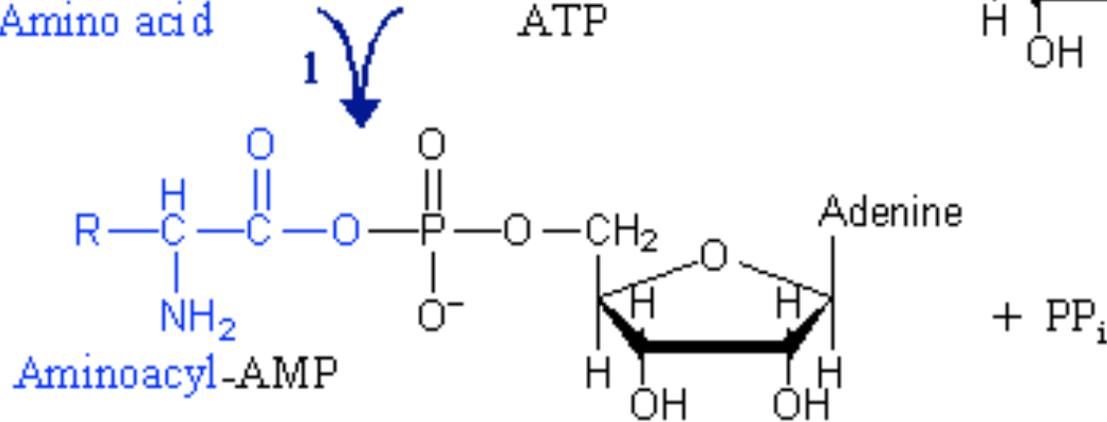

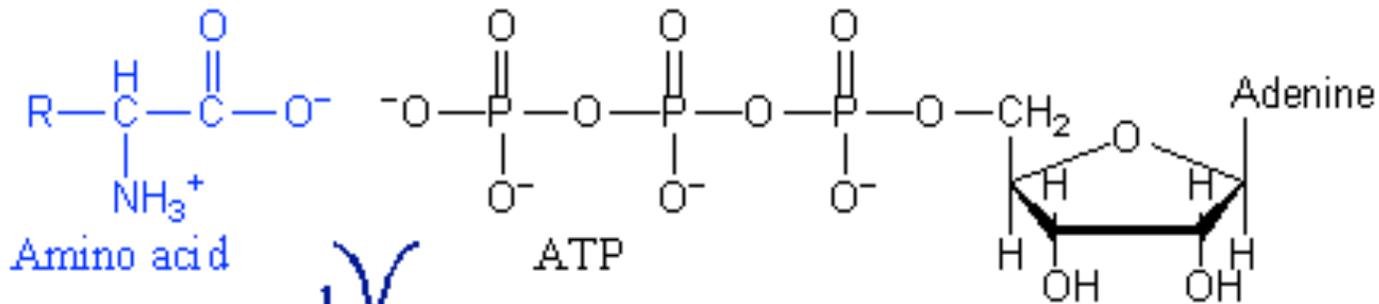

**Condensation**

**Biological  
Peptide Bond  
Formation**

# Aminoacylation of tRNAs

**Attaching amino acids to tRNAs:**

- Provides the adaptor for translation
- Activates the carboxyl group of the amino acid for peptide bond formation

**2 step process:**

**Step 1:** link amino acid to AMP

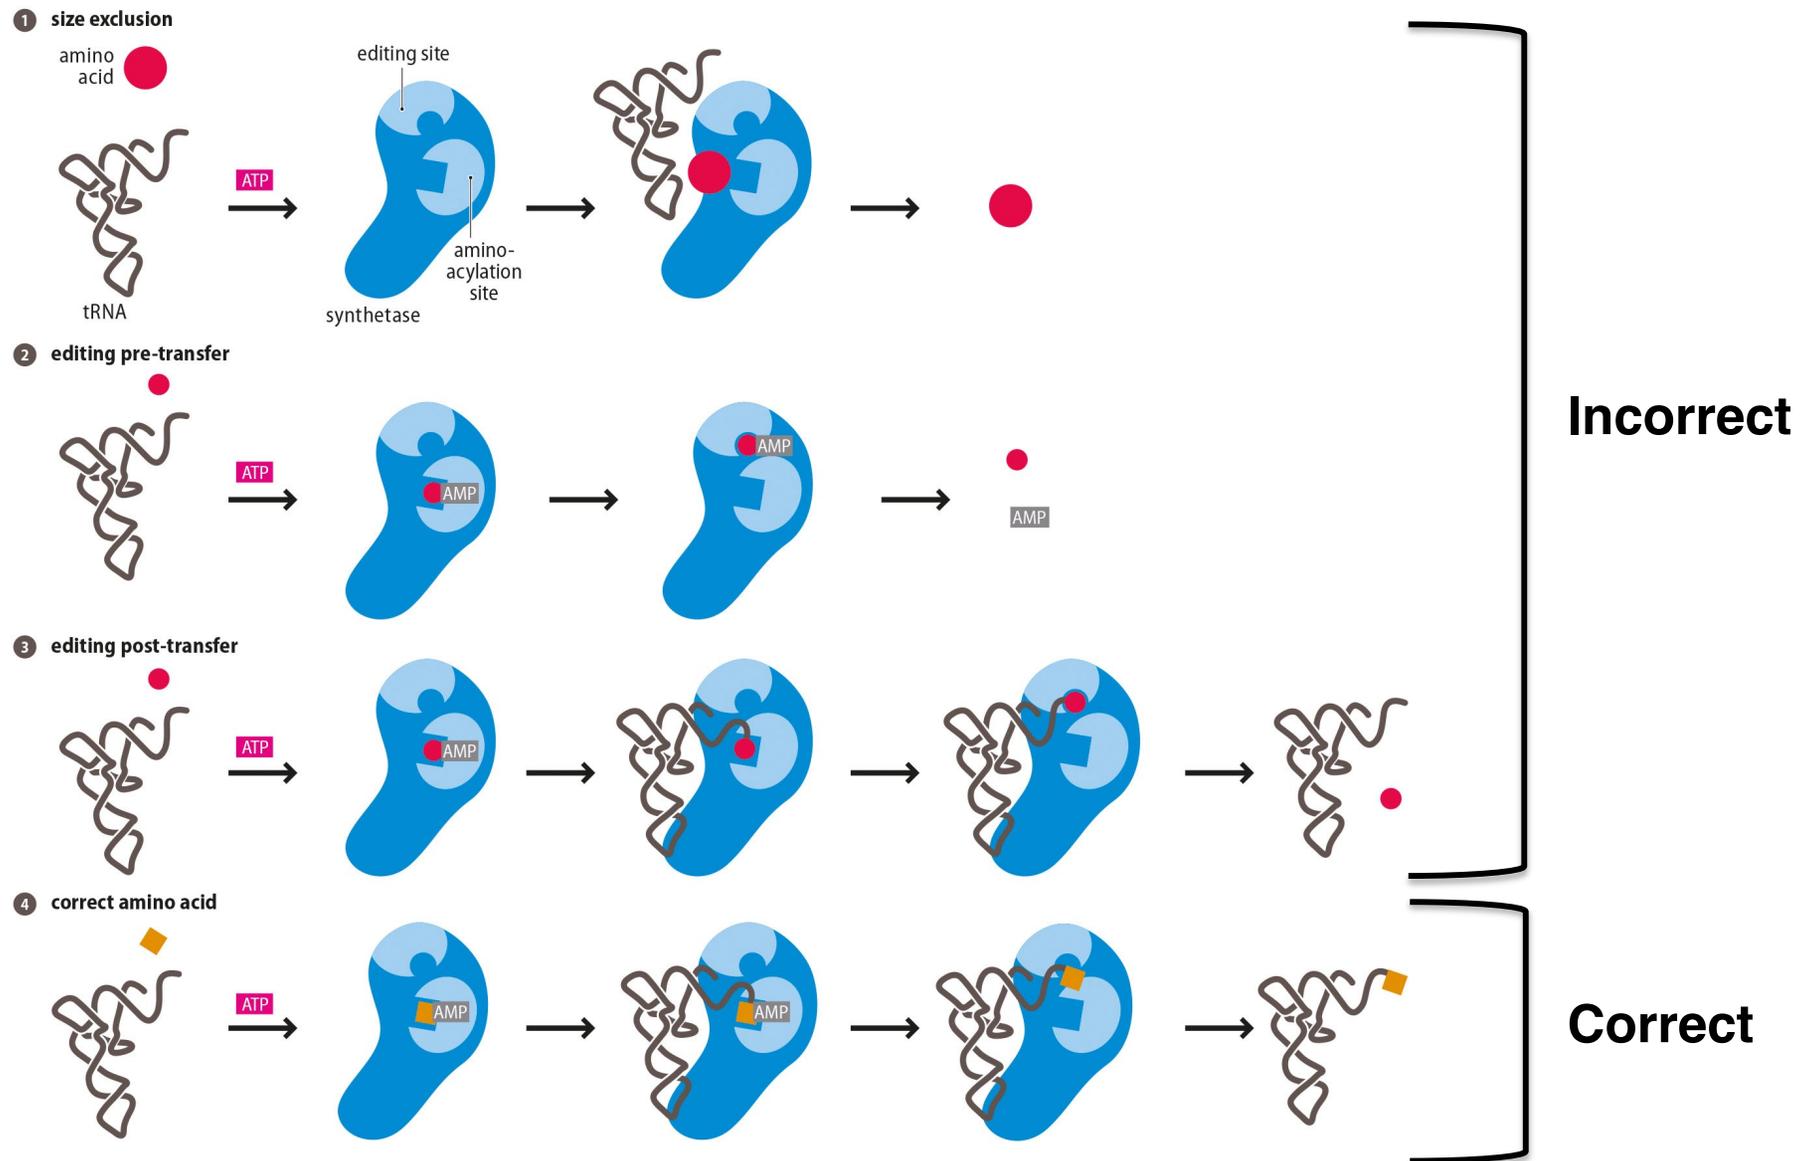

**Step 2:** amino-acyl group is transferred to the 3' hydroxyl group of the terminal adenylate of the tRNA

This process is catalyzed by **aminoacyl-tRNA synthetases**

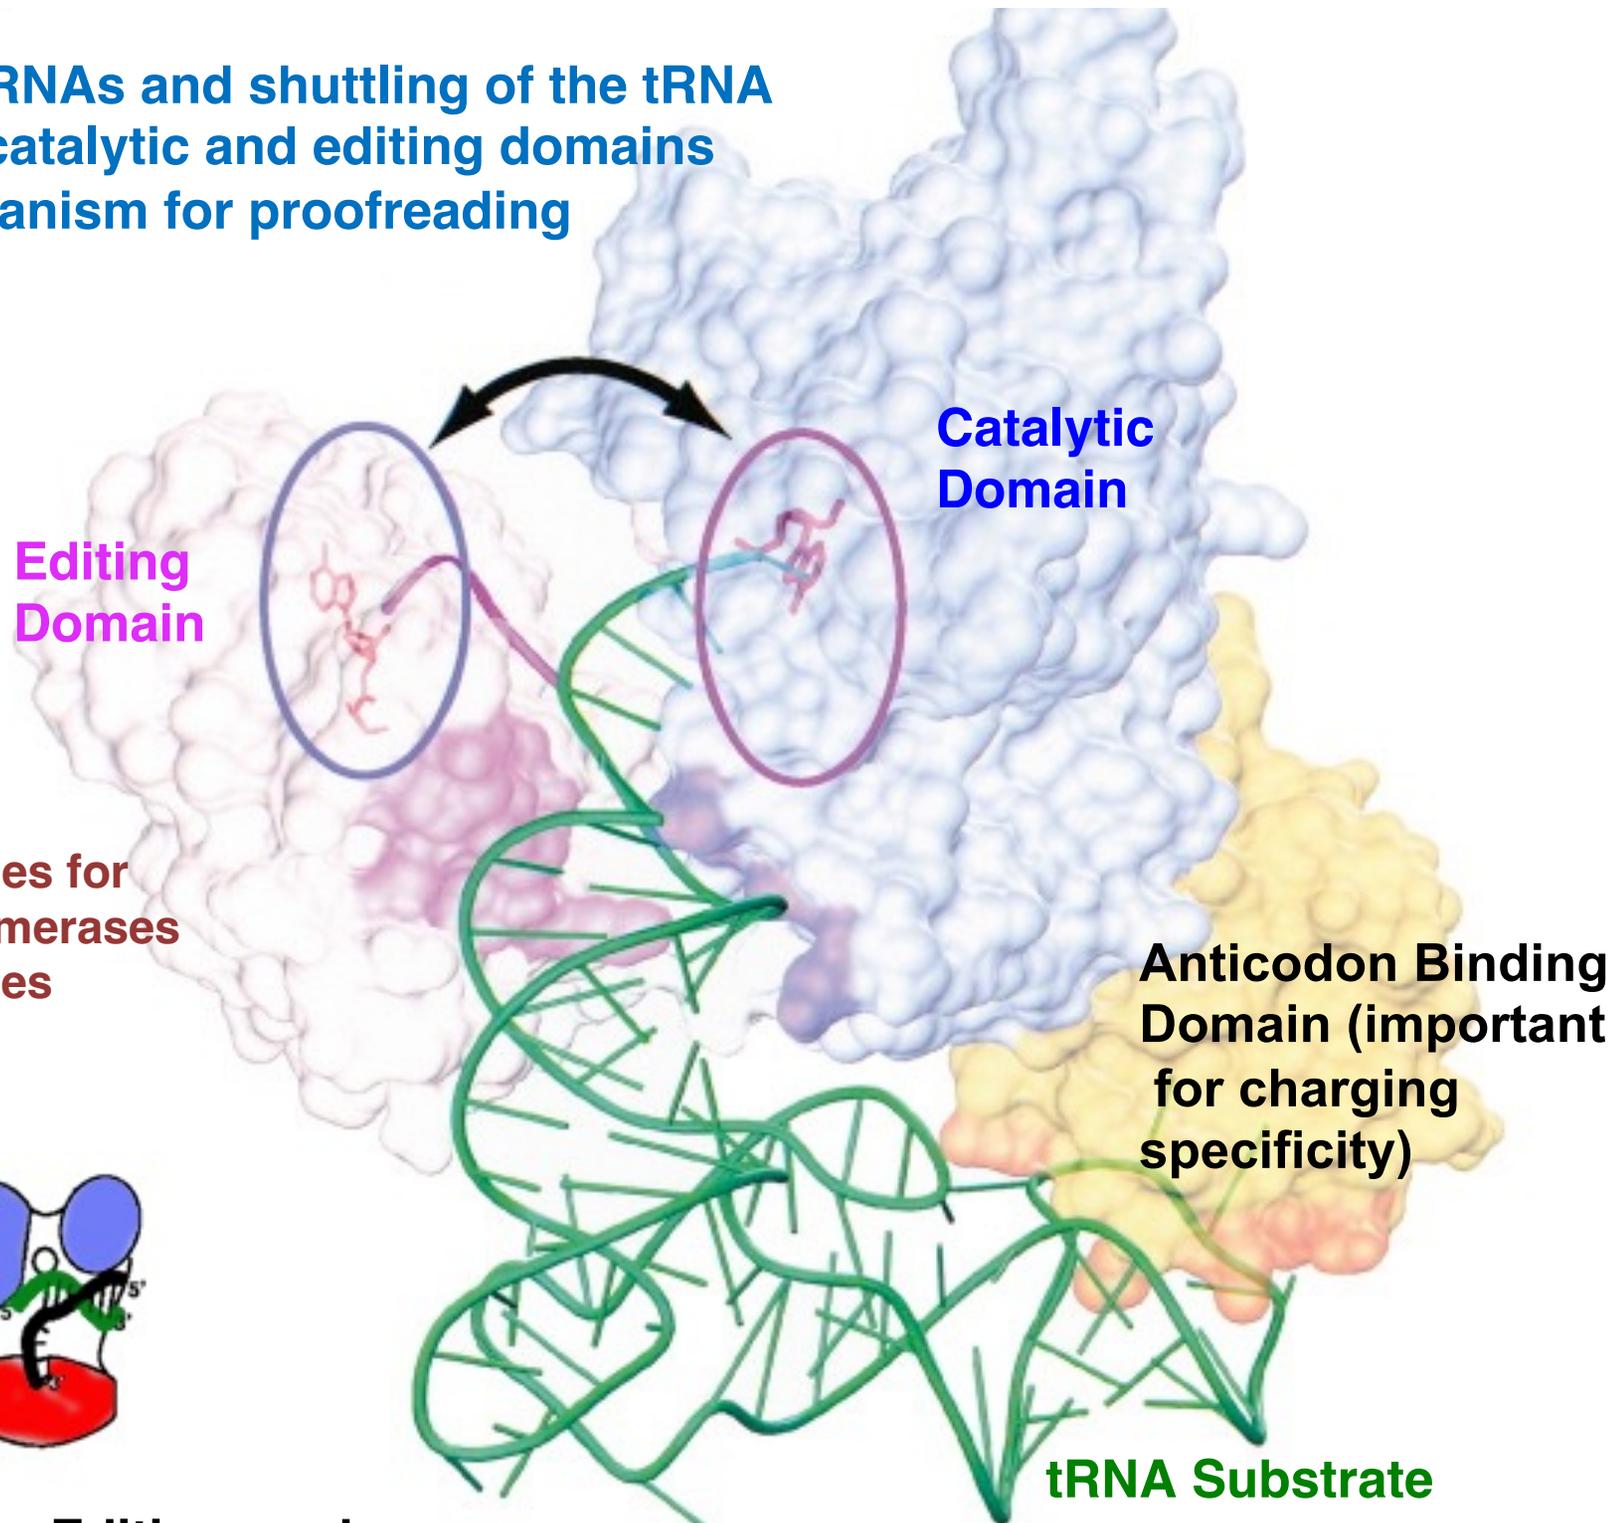

**Aminoacyl-tRNA Synthetase**

## Fidelity of tRNA aminoacylation

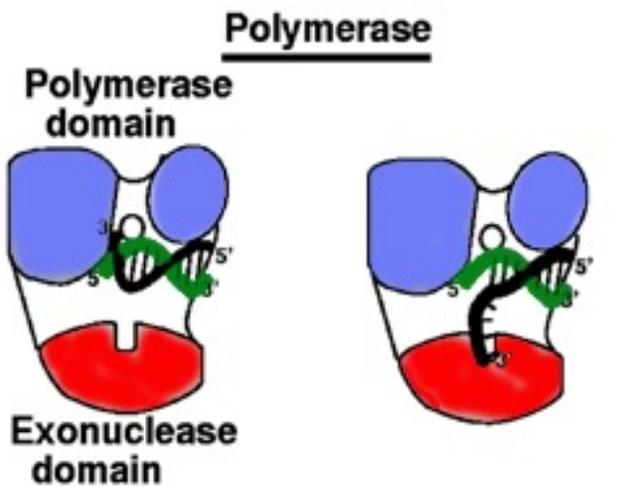

- The ribosome is not going to check that the right AA is attached to a tRNA
- Discrimination of the “right” AA on a single step is not greater than  $\sim 1/100$
- How do we get to the  $1/10^4$  error rate of protein synthesis?
- Aminoacyl tRNA synthetases use multiple steps to ensure charging fidelity

Recognition of tRNAs and shuttling of the tRNA 3'-end between catalytic and editing domains provides a mechanism for proofreading

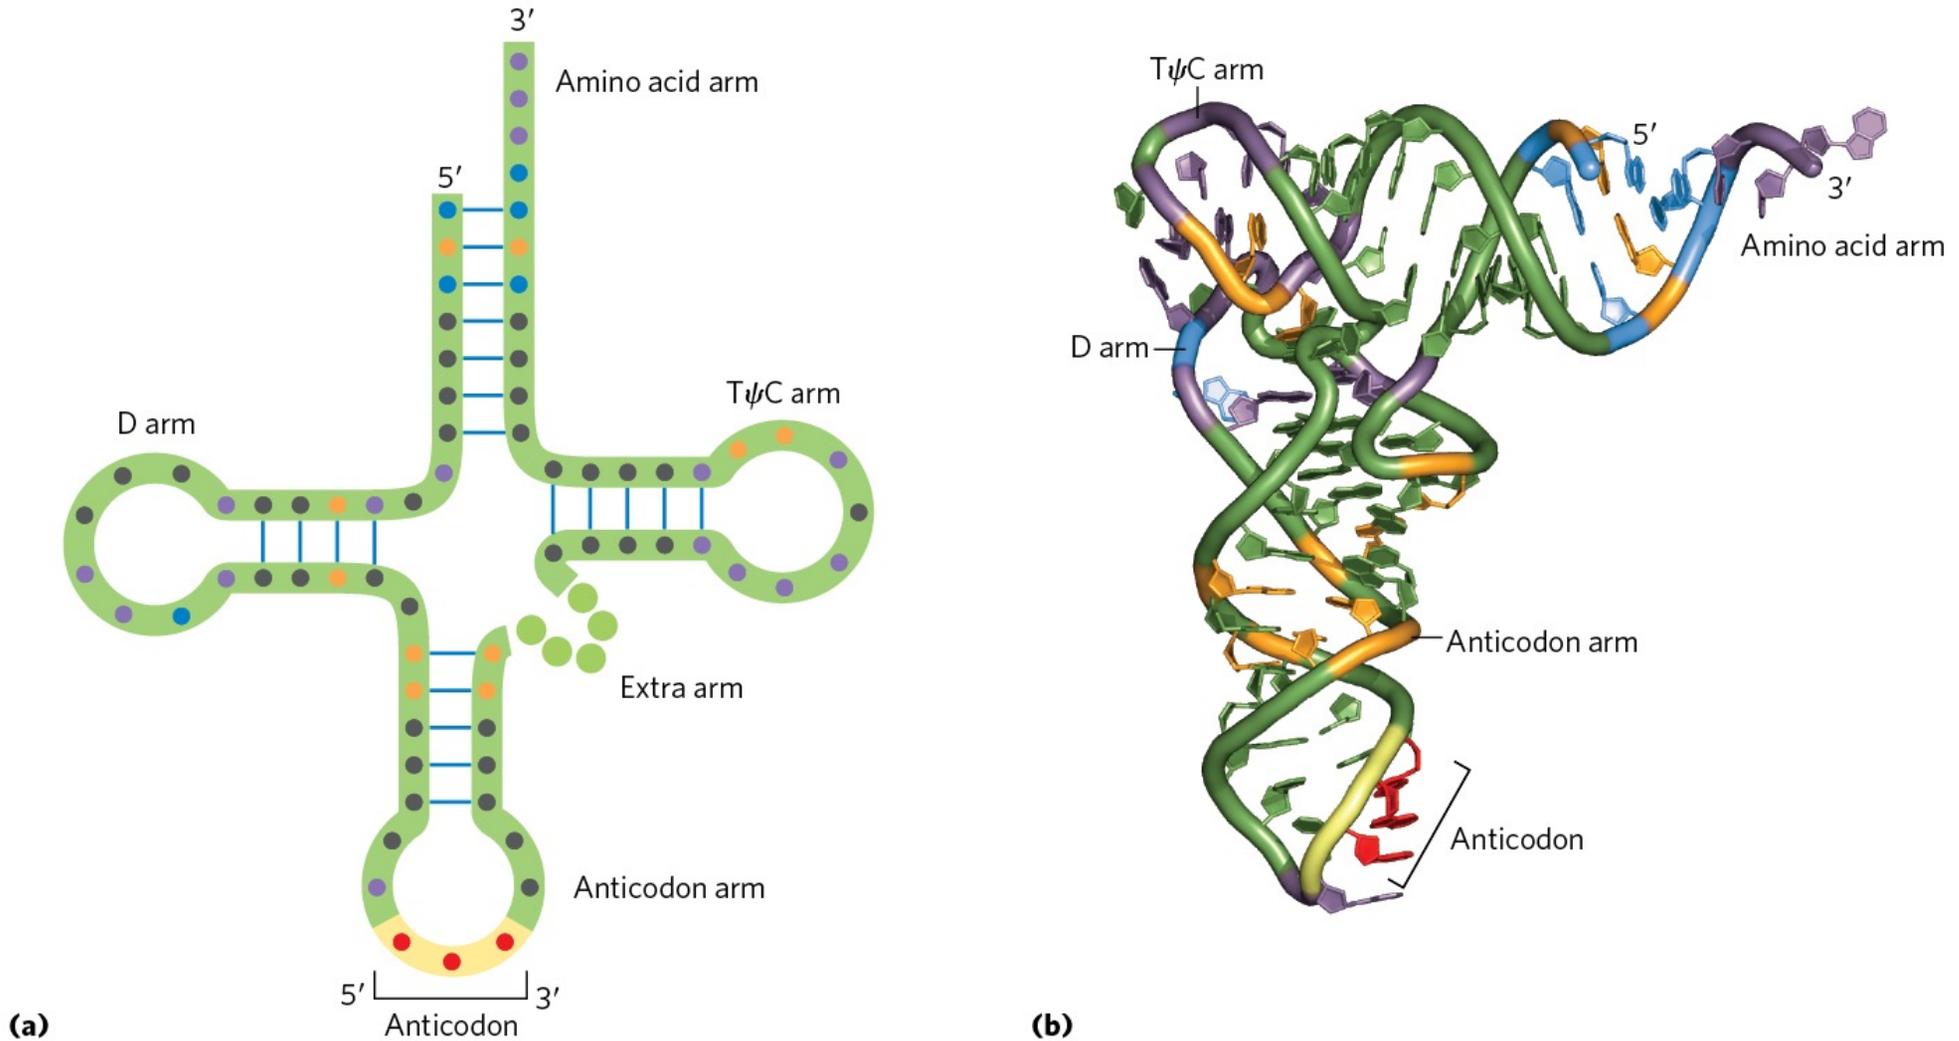

Functional similarities for editing in DNA Polymerases and tRNA synthetases

**Synthetic mode --> Editing mode**

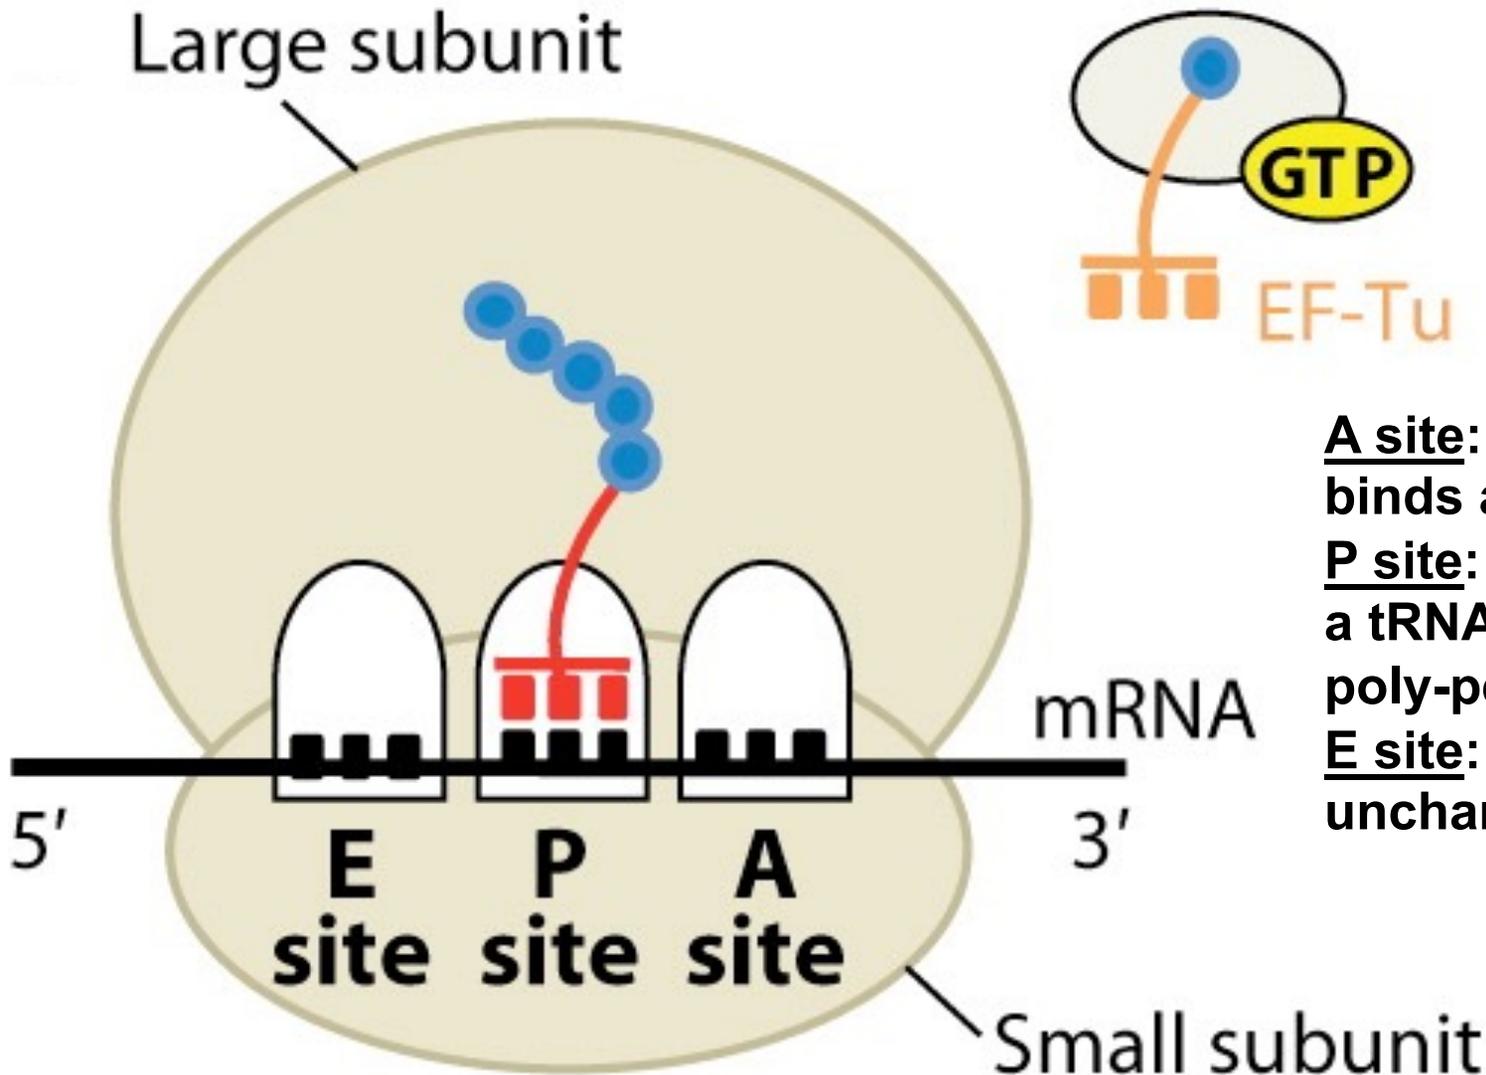

# Aminoacyl-tRNA synthetases must also be specific for the right tRNA

In addition to the anticodon sequence, **orange** and **blue** positions (above) are recognized by aminoacyl-tRNA synthetases

# The Ribosome – simple version

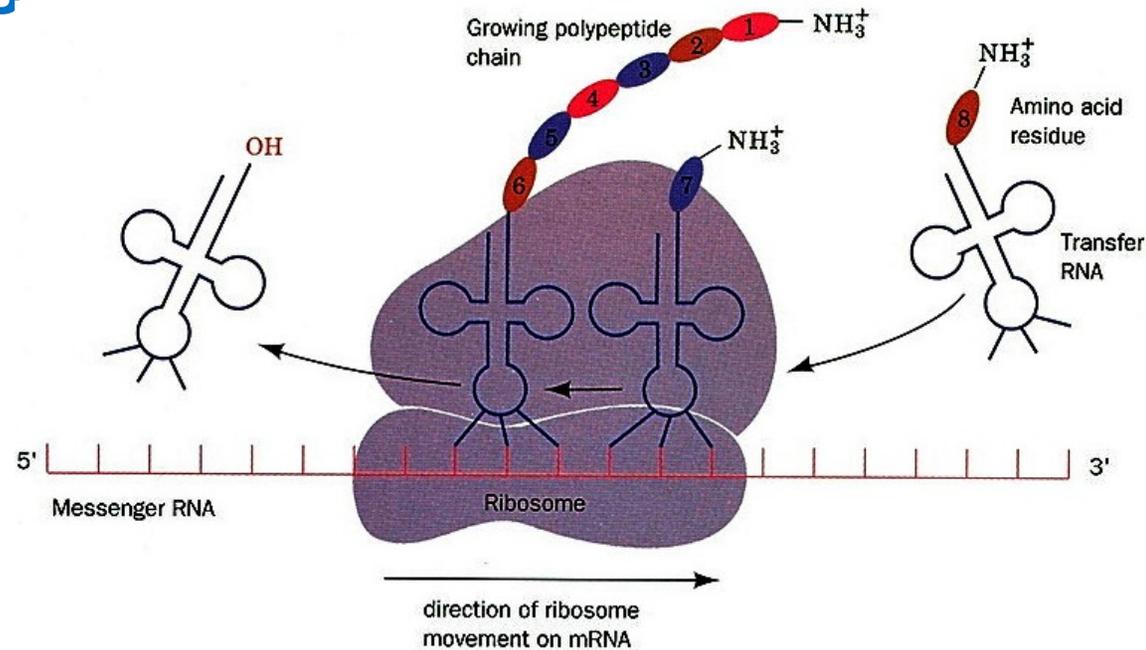

tRNAs are loaded in the ribosome A-site by elongation Factor EF-Tu

**A site:** aminoacyl site, binds aminoacyl-tRNA  
**P site:** peptidyl site, binds a tRNA connected to a poly-peptide chain  
**E site:** exit site, binds uncharged tRNAs

What is wrong with this picture ?

**A: There is no Exit site shown on the ribosome**

**B: tRNAs are shown entering into the P site, not the A site**

**C: tRNAs form 5'-3'/5'-3' anticodon/codon interactions**

**D: The ribosome moves in the wrong direction**

# Regulation of bacterial translation initiation by RNA Structures that bind metabolites and change structure upon metabolite binding (aka Riboswitches): example of a Lysine-responsive riboswitch

**A – Low cellular Lysine levels -> Translation of Lysine metabolic genes because the RBS is available**

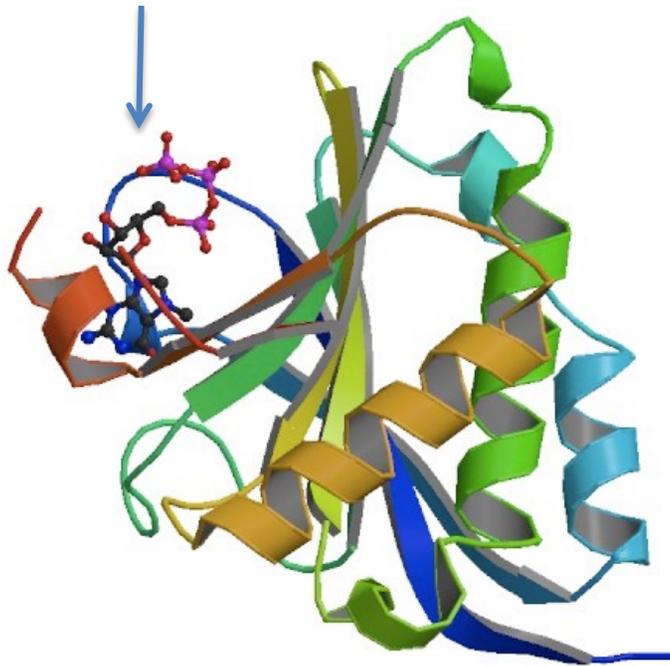

**B – High cellular Lysine levels -> Repression of translation of Lysine Metabolic Genes because the RBS is sequestered**

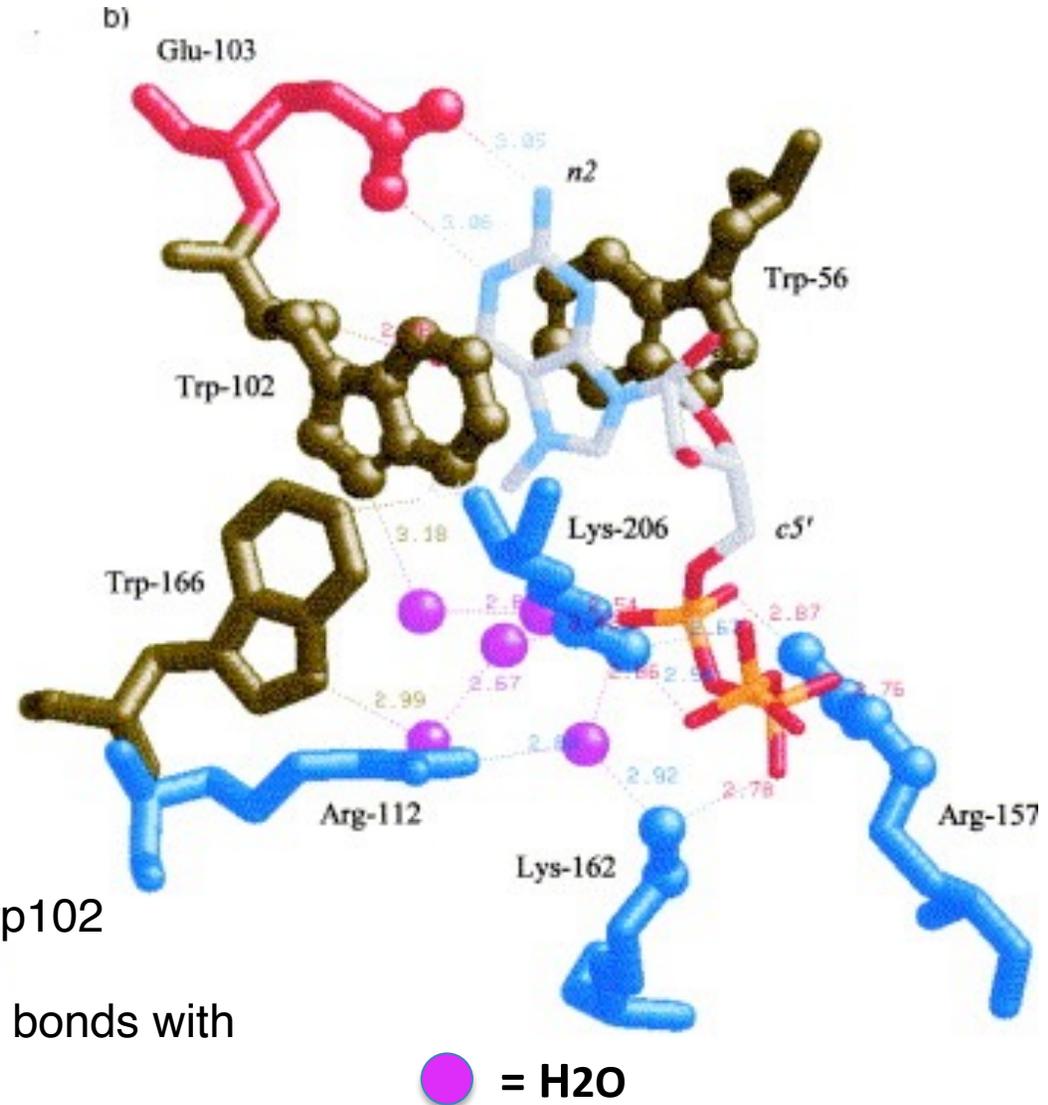

# Recognition of the 5'-cap structure of eukaryotic mRNAs by eIF4e

Cap binding pocket is on the concave surface of the protein – allows easy entry of the mRNA 5'-end

PDB ID = 1L8B  
Niedzwiecka et al. J.Mol.Biol. 2002

- base sandwich-stacking between Trp56 and Trp102
- formation of three Watson–Crick-like hydrogen bonds with Glu103 and backbone NH of Trp102
- Hydrophobic interaction of the 7-methyl group with Trp166
